FACTS

Predict how many cars are needed per hub ? Regression prob

users = 2525

cars = 140

reservations = 17 534

hubs_green = openbare hubs } 45 hubs

hubs_red = privé hub

cities =

Questions that pop up =

coördinates lon, lat of all hubs

category hub green/red

distance between hubs

can you find reason why these hub locations are so important ?

political voting behavior. in these locations.

ratio van zelfstandigen die werken en die regio.

at what hours are these cars mostly used.

if evening will it be a one-way trip, then taxi home after a booze night.

the hubs have fleet operators = cleaning
- info
- charged.

what reasons a User rent Sixter ?

a hub can hold 1 or more Sixter cars.

2 states = car in drive DRIVING
car in pickup
car in lease
car in recharge. CHARGING

first understand the dataset. make report + visualisations.

create a server.

start a simple Regression notebook.

↳ ~~too~~ only rough data cleanup

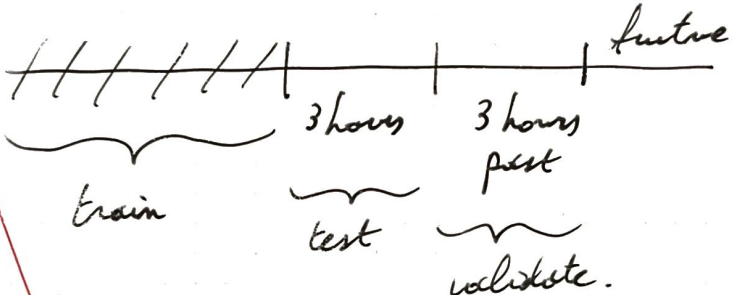
↳ getting a prediction model asap

↳ then iterate on top of this

Feature engineering

Maybe create a graph DB.

at what timeframe do we need to predict the amount of cars?



How does the target look like?

what is the max amount of cars allowed per hub?

start creating a powerpoint presentation or in the notebook itself :)
